 - **Deep Learning**
Provide ability to handling real-world scenarios
 - **Reinforcement Learning**
Provide ability to make decision in long-term, using previous experiences in complex and robust scenarios
- Combining two techniques
 - Able to learn policy continuously from their experience
 - No need for manual engineering, use data they collects

- Variance in **visual and physical property of objects**

- Variance in **visual and physical property of objects**
 - Hardness of object (Soft or Hard)
 - Surface Characteristics (Slippery, Sticky, ...)
 - Color Variation
 - Shape Variation
 - ...

- Focused on learning narrow, individual tasks
 - hitting a ball
 - opening door
 - throwing objects
 - ...
- ⇒ Use **Grasping** to achieve *generalization*
- Approached the grasping task as predicting a *grasp pose*
 - 1 Observe the scene (*Normally, using a depth camera*)
 - 2 Choose best location to grasp
 - 3 Reach the location (open-loop setting)

- Focused on learning narrow, individual tasks

- hitting a ball
- opening door
- throwing objects
- ...

⇒ Use **Grasping** to achieve *generalization*

- Approached the grasping task as predicting a *grasp pose*

- 1 Observe the scene (*Normally, using a depth camera*)
 - 2 Choose best location to grasp
 - 3 Reach the location (open-loop setting)
- Different with how humans and animals behave
 - Grasp is a **dynamical process** that sense and control at each stage

Use Reinforcement Learning with Deep Neural Network
to **perform pre-grasp manipulation,**
response to dynamic disturbances,
and **learn grasping in a generic framework**
that makes minimal assumptions about the task

- **Closed-loop condition** (With feedback, *Morrison, et al.*)
 - For the other papers work on closed-loop grasping, they deals with servoing problems.
 - This paper focuses on making generalized RL algorithm
 - In practice, it makes Kalashnikov et al.'s method (this method) to autonomously acquire complicated grasping strategy

- **Closed-loop condition** (With feedback, *Morrison, et al.*)
 - For the other papers work on closed-loop grasping, they deal with servoing problems.
 - This paper focuses on making a generalized RL algorithm
 - In practice, it makes Kalashnikov et al.'s method (this method) to autonomously acquire a complicated grasping strategy
- **Self-supervised learning task**
 - Compare to previous work (by Zeng et al.), Kalashnikov et al. utilize more general action space
 - Actions consist of end-effector **Cartesian motion** and **gripper opening/closing**

- General Formulation of Robotic Manipulation:
Based on **Markov Decision Process (MDP)**
 - partially observed formulation (POMDP) is more general.
 - However, assuming current observation contains all necessary information for this task, it is sufficient to use MDP.

- General Formulation of Robotic Manipulation:
Based on **Markov Decision Process (MDP)**
 - partially observed formulation (POMDP) is more general.
 - However, assuming current observation contains all necessary information for this task, it is sufficient to use MDP.
- MDP have a **general and powerful formalism** for decision making problems.
However, it is **hard to train**

- General Formulation of Robotic Manipulation:
Based on **Markov Decision Process (MDP)**
 - partially observed formulation (POMDP) is more general.
 - However, assuming current observation contains all necessary information for this task, it is sufficient to use MDP.
- MDP have a **general and powerful formalism** for decision making problems.
However, it is **hard to train**
- For each step of MDP:
 - 1 Observes Image from robot's camera (see Fig. 1)
 - 2 choose a gripper command, Reward:
 - failed grasp: reward of 0
 - successful grasp: reward of 1Defined *success* when the robot holds the object above a certain height

Figure 1: Configuration of robot cell, with a sample observation image on top-right box

Overview of Model Architecture: Algorithm Selection

- Usually, Generalization needs diverse data
 - However, recollecting experience on numerous objects after every policy update is impractical
 - Reason for **not using on-policy algorithm**

Overview of Model Architecture: Algorithm Selection

- Usually, Generalization needs diverse data
 - However, recollecting experience on numerous objects after every policy update is impractical
 - Reason for **not using on-policy algorithm**
- Using **scalable off-policy algorithm** based on Q-learning
 - actor-critic algorithm are popular for handling continuous actions
 - However, Kalashnikov et al. found **scalable and more stable ways** to train only Q-function

Overview of Model Architecture: Algorithm Selection

- Usually, Generalization needs diverse data
 - However, recollecting experience on numerous objects after every policy update is impractical
 - Reason for **not using on-policy algorithm**
- Using **scalable off-policy algorithm** based on Q-learning
 - actor-critic algorithm are popular for handling continuous actions
 - However, Kalashnikov et al. found **scalable and more stable ways** to train only Q-function
- Large Dataset and Network (See Fig. 2)
 - Kalashnikov et al. devised **distributed** training system (with 7 robots)
 - **Asynchronously update** target values, collect **on-policy data**, reloads **off-policy data** from previous experiences, and train network on both data stream.

Overview of Model Architecture: Algorithm Selection

Figure 2: Distributed Reinforcement Learning infrastructure for QT-Opt.

- **On-policy Learning** learns the value of the policy being **carried out by the agent**, including the exploration steps.
e.g. SARSA(State-Action-Reward-State-Action) (See Fig. 3)

- **On-policy Learning** learns the value of the policy being **carried out by the agent**, including the exploration steps.
e.g. SARSA(State-Action-Reward-State-Action) (See Fig. 3)
- **Off-policy Learning** learns the value of the optimal policy **independently of the agent's action**
e.g. Q-Learning (See Fig. 4)

controller SARSA(S, A, γ, α)

inputs:

S is a set of states

A is a set of actions

γ the discount

α is the step size

internal state:

real array $Q[S, A]$

previous state s

previous action a

begin

initialize $Q[S, A]$ arbitrarily

observe current state s

select action a using a policy based on Q

repeat forever:

 carry out an action a

 observe reward r and state s'

 select action a' using a policy based on Q

$Q[s, a] \leftarrow Q[s, a] + \alpha(r + \gamma Q[s', a'] - Q[s, a])$

$s \leftarrow s'$

$a \leftarrow a'$

end-repeat

end

Figure 3: SARSA Algorithm

- Continuous action version of Q-Learning
 - For **scalable** learning and optimized for **stability**
 - To handle **large amount of off-policy image data** for complex tasks

- **state:** $s \in \mathcal{S}$ (*Image Observations*)
- **action:** $a \in \mathcal{A}$ (*Robot Arm Motions and Gripper commands*)
- at **each time step** t
 - 1 Choose an action
 - 2 transition to new state
 - 3 receive reward $\gamma(s_t, a_t)$

- Need to solve for Optimal Q-function: Minimize Bellman Error

$$\mathcal{E}(\theta) = \mathbb{E}_{(s,a,s') \sim p(s,a,s')} [\mathcal{D}(\mathcal{Q}_\theta(s,a), \mathcal{Q}_\mathcal{T}(s,a,s'))]$$

Where $\mathcal{Q}_\mathcal{T}(s,a,s') = r(s,a) + \gamma V(s')$ (*target value*)

- \mathcal{D} : divergence metric (squared difference for Q-Learning)
- Expectation is taken under the distribution over all previously observed transition

- Use **two target network** to improve stability
 - Maintaining two lagged version of the parameter vector $\theta, \bar{\theta}_1, \bar{\theta}_2$
 - $\bar{\theta}_1$: exponential moving averaged version of θ , averaging constant: 0.9999
 - $\bar{\theta}_2$: lagged version of $\bar{\theta}_1$, lagged by 6000 gradient steps

- Use **two target network** to improve stability
 - Maintaining two lagged version of the parameter vector $\theta, \bar{\theta}_1, \bar{\theta}_2$
 - $\bar{\theta}_1$: exponential moving averaged version of θ , averaging constant: 0.9999
 - $\bar{\theta}_2$: lagged version of $\bar{\theta}_1$, lagged by 6000 gradient steps
- Compute target value by
$$V(s') = \min_{i=1,2} Q_{\bar{\theta}_i}(s', \arg \max_{a'} Q_{\bar{\theta}_1}(s', a'))$$

- Use **two target network** to improve stability
 - Maintaining two lagged version of the parameter vector $\theta, \bar{\theta}_1, \bar{\theta}_2$
 - $\bar{\theta}_1$: exponential moving averaged version of θ , averaging constant: 0.9999
 - $\bar{\theta}_2$: lagged version of $\bar{\theta}_1$, lagged by 6000 gradient steps
- Compute target value by
$$V(s') = \min_{i=1,2} Q_{\bar{\theta}_i}(s', \arg \max_{a'} Q_{\bar{\theta}_i}(s', a'))$$
- the policy is recovered by $\pi(s) = \arg \max_a Q_{\bar{\theta}_1}(s, a)$

- Use **two target network** to improve stability
 - Maintaining two lagged version of the parameter vector $\theta, \bar{\theta}_1, \bar{\theta}_2$
 - $\bar{\theta}_1$: exponential moving averaged version of θ , averaging constant: 0.9999
 - $\bar{\theta}_2$: lagged version of $\bar{\theta}_1$, lagged by 6000 gradient steps
- Compute target value by
$$V(s') = \min_{i=1,2} Q_{\bar{\theta}_i}(s', \arg \max_{a'} Q_{\bar{\theta}_i}(s', a'))$$
- the policy is recovered by $\pi(s) = \arg \max_a Q_{\bar{\theta}_1}(s, a)$
- After collects samples from environment interaction, then perform off-policy training on all samples collected
 - Problem: Large-scale learning (Technically Difficult)
 - Solution: Use **Parallel Asynchronous** version (which leads ability to scale up the process)

- Difficult to deal with continuous actions, e.g. continuous gripper motion

- Difficult to deal with continuous actions, e.g. continuous gripper motion
- *Previous Solutions:*
 - using a second network that "amortize" the maximization
 - constraining the Q-function to be convex in a , so that makes the function to easily find maximum analytically

- Difficult to deal with continuous actions, e.g. continuous gripper motion
- *Previous Solutions:*
 - using a second network that "amortize" the maximization
 - constraining the Q-function to be convex in a , so that makes the function to easily find maximum analytically
- problem of previous solutions
 - Unstable: problematic for large-scale RL tasks where running hyperparameter sweeps is very expensive
 - Action-convex value functions are poor fit for complex manipulation tasks

- To **maintain the generality of non-convex Q-function** while **not using a second maximizer network**
- the Bellman equation is evaluated with stochastic optimization
 - handles non-convex and multimodal optimization landscapes

- To **maintain the generality of non-convex Q-function** while **not using a second maximizer network**
- the Bellman equation is evaluated with stochastic optimization
 - handles non-convex and multimodal optimization landscapes
- QT-Opt
 - $\pi_{\bar{\theta}_1}(s)$ is evaluated by running stochastic optimization over a , using $\mathcal{Q}_{\bar{\theta}_1}(s, a)$ as the objective value

- To **maintain the generality of non-convex Q-function** while **not using a second maximizer network**
- the Bellman equation is evaluated with stochastic optimization
 - handles non-convex and multimodal optimization landscapes
- QT-Opt
 - $\pi_{\bar{\theta}_1}(s)$ is evaluated by running stochastic optimization over a , using $\mathcal{Q}_{\bar{\theta}_1}(s, a)$ as the objective value
 - Use Cross-Entropy Method
 - ① samples a batch of N at each iteration
 - ② fits a Gaussian distribution to the best $M < N$ samples
 - ③ Samples next batch of N from the Gaussian

- To **maintain the generality of non-convex Q-function** while **not using a second maximizer network**
- the Bellman equation is evaluated with stochastic optimization
 - handles non-convex and multimodal optimization landscapes
- QT-Opt
 - $\pi_{\bar{\theta}_1}(s)$ is evaluated by running stochastic optimization over a , using $Q_{\bar{\theta}_1}(s, a)$ as the objective value
 - Use Cross-Entropy Method
 - ① samples a batch of N at each iteration
 - ② fits a Gaussian distribution to the best $M < N$ samples
 - ③ Samples next batch of N from the Gaussian
 - easy to parallelize
 - moderately robust to local optima

- Requires large amount of diverse data to generalize over new scenes and objects for the image-based policy

- Requires large amount of diverse data to generalize over new scenes and objects for the image-based policy
- Needs of Distributed System (See Fig. 2)

- Requires large amount of diverse data to generalize over new scenes and objects for the image-based policy
- Needs of Distributed System (See Fig. 2)
 - ① Replay buffer stores both **off-line data** (from disk) and on-going experiments' data (**on-line data**)

- Requires large amount of diverse data to generalize over new scenes and objects for the image-based policy
- Needs of Distributed System (See Fig. 2)
 - ① Replay buffer stores both **off-line data** (from disk) and on-going experiments' data (**on-line data**)
 - ② Data in buffer labeled with target Q-value using a set of 1000 "bellman updater" jobs

- Requires large amount of diverse data to generalize over new scenes and objects for the image-based policy
- Needs of Distributed System (See Fig. 2)
 - ① Replay buffer stores both **off-line data** (from disk) and on-going experiments' data (**on-line data**)
 - ② Data in buffer labeled with target Q-value using a set of 1000 "bellman updater" jobs
 - ③ Store the labeled sample in the training buffer
 - Some samples in the training buffer are **labeled with lagged version** of the Q-network

- Requires large amount of diverse data to generalize over new scenes and objects for the image-based policy
- Needs of Distributed System (See Fig. 2)
 - ① Replay buffer stores both **off-line data** (from disk) and on-going experiments' data (**on-line data**)
 - ② Data in buffer labeled with target Q-value using a set of 1000 "bellman updater" jobs
 - ③ Store the labeled sample in the training buffer
 - Some samples in the training buffer are **labeled with lagged version** of the Q-network
 - ④ Training workers pull the labeled sample from the training buffer **randomly** to update the Q-function
 - each training workers compute gradient that sent to parameter server asynchronously

- Requires large amount of diverse data to generalize over new scenes and objects for the image-based policy
- Needs of Distributed System (See Fig. 2)
 - ① Replay buffer stores both **off-line data** (from disk) and on-going experiments' data (**on-line data**)
 - ② Data in buffer labeled with target Q-value using a set of 1000 "bellman updater" jobs
 - ③ Store the labeled sample in the training buffer
 - Some samples in the training buffer are **labeled with lagged version** of the Q-network
 - ④ Training workers pull the labeled sample from the training buffer **randomly** to update the Q-function
 - each training workers compute gradient that sent to parameter server asynchronously
- Empirically, it requires up to **15M gradient steps** to train effective Q-function due to **complexity of the task** and **the size of dataset and model**

- Policy
 - locate object
 - position for grasping (pre-grasping manipulation, if needed)
 - pick up (regrasping, if needed)
 - Pull up the object
 - signal termination

- Policy
 - locate object
 - position for grasping (pre-grasping manipulation, if needed)
 - pick up (regrasping, if needed)
 - Pull up the object
 - signal termination
- Reward
 - only indicates whether or not an object was successfully picked up

- Policy
 - locate object
 - position for grasping (pre-grasping manipulation, if needed)
 - pick up (regrasping, if needed)
 - Pull up the object
 - signal termination
- Reward
 - only indicates whether or not an object was successfully picked up
- End-to-End approach of grasping!!
 - no prior knowledge about object, physics, or motion planning
 - model itself autonomously extract the knowledges from data

- state observation $s \in \mathcal{S}$ includes:
 - robot's current camera observation (RGB image, res: 472×472) from over-the-shoulder single-lens camera
 - current status of gripper (binary)
 - vertical position of the gripper relative to the floor

- state observation $s \in \mathcal{S}$ includes:
 - robot's current camera observation (RGB image, res: 472×472) from over-the-shoulder single-lens camera
 - current status of gripper (binary)
 - vertical position of the gripper relative to the floor
- action $a = (t, r, g_{open}, g_{close}, e) \in \mathcal{A}$ includes:
 - vector in Cartesian space $t \in \mathbb{R}^3$ (desired change in the gripper position)
 - change in azimuthal angle via sine-cosine encoding, $r \in \mathbb{R}^2$
 - binary gripper open and close command, g_{open}, g_{close}
 - termination command, e

- 1: if gripper carries the object up above certain height at the end of the episode
- 0: otherwise

- 1: if gripper carries the object up above certain height at the end of the episode
- 0: otherwise
- penalty (-0.05): for all time steps prior to termination
 - emits termination action
 - exceed the maximum number of time steps(20)

- 1: if gripper carries the object up above certain height at the end of the episode
- 0: otherwise
- penalty (-0.05): for all time steps prior to termination
 - emits termination action
 - exceed the maximum number of time steps(20)
- delayed and sparse reward function is challenging, but more practical for automated self-supervision

Environment Settings: Q-function

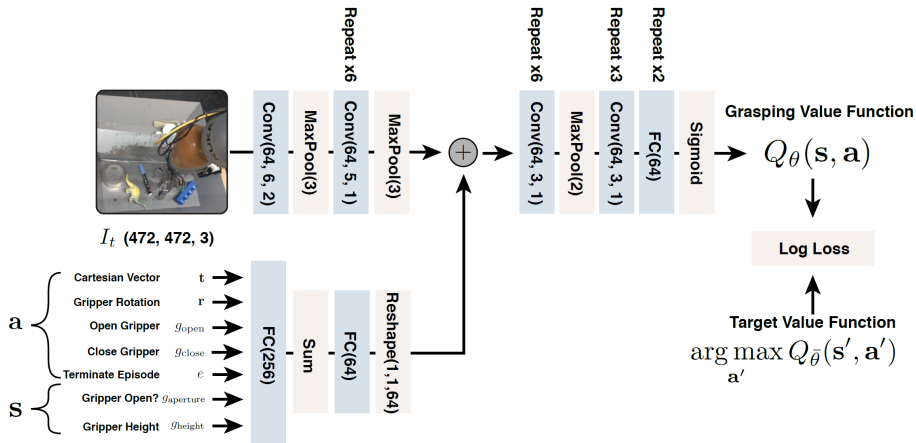

Figure 5: Neural Network Architecture for Q-Fuction.

It has total of 1.2M parameters. The image is processed with convolution filters, and the other inputs are processed by fully connected layer, then concatenated with the image

- Need to collect data on sufficiently large and diverse set of objects
- Use multiple robots and multiple experiments to collect such data
 - Took four months, 800 Robot hrs
 - Collected during multiple separated experiments, and each experiment reused the data from the previous one

- Need to collect data on sufficiently large and diverse set of objects
- Use multiple robots and multiple experiments to collect such data
 - Took four months, 800 Robot hrs
 - Collected during multiple separated experiments, and each experiment reused the data from the previous one
- Initialize policy
 - Used weak scripted exploration policy to bootstrap data collection
 - Still random, but biased toward reasonable grasping
 - Success Rate: Around 15-30%
 - Switching to QT-Opt once it reach 50% of success rate

- ① Performance on unseen object (quantitative)
- ② Performance comparison with other self-supervised grasping system (quantitative)
- ③ Manipulation strategies which carried out meaningful pre-grasp manipulation (quality)

- Used two evaluation protocol
 - Each robots make 102 grasp attempts on test objects.
 - grasp attempts last for up to 20 times steps
 - any grasped objects returned back to the bin
 - Experimentally, the robot made grasp attempts on a various objects, not picking one objects
 - Might have confounding effects

- Used two evaluation protocol
 - Each robots make 102 grasp attempts on test objects.
 - grasp attempts last for up to 20 times steps
 - any grasped objects returned back to the bin
 - Experimentally, the robot made grasp attempts on a various objects, not picking one objects
 - Might have confounding effects
 - bin emptying
 - single robot unload a bin with 28 test objects, using 30 grasp attempts
 - Repeated for five times
 - Success rate is reported over the first 10, 20, and 30 grasp attempts

Method	Dataset	Test	Bin emptying		
			first 10	first 20	first 30
QT-Opt (ours)	580k off-policy + 28k on-policy	96%	88%	88%	76%
Levine et al. [27]	900k grasps from Levine et al. [27]	78%	76%	72%	72%
QT-Opt (ours)	580k off-policy grasps only	87%			
Levine et al. [27]	400k grasps from our dataset	67%			

Figure 6: Result of Quantitative Analysis Result.

Left half indicates the result of re-deposit grasping tasks, the right half indicates the results of bin emptying experiments

(See Fig. 6)

- Usage of on-policy training
 - on-policy joint finetuning provides better Performance
 - Kalashnikov et al. analyzed that on-policy helps the model to remove "hard negatives"

(See Fig. 6)

- Usage of on-policy training
 - on-policy joint finetuning provides better Performance
 - Kalashnikov et al. analyzed that on-policy helps the model to remove "hard negatives"
- Bin emptying
 - successfully empty all objects within 30 grasps for 2/5 trials (Kalashnikov et al.)
 - Previous method (Levine et al.) successfully empty for 1/5 trials
 - lower success rate for 30 grasp due to the algorithm tend to grasp easy one first

(See Fig. 6)

- Compare with Levine et al.
 - greedily optimized for grasp success at the next grasp
 - does not control the opening and closing of gripper
 - does not explain about pregrasp manipulation

(See Fig. 6)

- Compare with Levine et al.
 - greedily optimized for grasp success at the next grasp
 - does not control the opening and closing of gripper
 - does not explain about pregrasp manipulation
 - action representation is different, making the format of dataset different

(See Fig. 6)

- Compare with Levine et al.
 - greedily optimized for grasp success at the next grasp
 - does not control the opening and closing of gripper
 - does not explain about pregrasp manipulation
 - action representation is different, making the format of dataset different
 - tested on both Levine et al.'s data format and this article's format
 - either way, it is worse than Kalashnikov et al's work

Video: <https://sites.google.com/view/qtopt>

- Singulation and pregrasp manipulation
 - Change position of object to make them easier to grasp

- Singulation and pregrasp manipulation
 - Change position of object to make them easier to grasp
- Regrasping
 - open and close the gripper at any time
 - detect failed or unstable grasp earlier
so that let the robots to grasp more securely

- Singulation and pregrasp manipulation
 - Change position of object to make them easier to grasp
- Regrasping
 - open and close the gripper at any time
 - detect failed or unstable grasp earlier
so that let the robots to grasp more securely
- Handling disturbance and Dynamic objects
 - grasp object that moving dynamically (e.g. balls)
 - though the sequence intentionally disturbed,
it still able to grasp the object

- Singulation and pregrasp manipulation
 - Change position of object to make them easier to grasp
